ABSTRACT. The “quantum duality principle” states that a quantisation of a Lie bialgebra provides also a quantisation of the dual formal Poisson group and, conversely, a quantisation of a formal Poisson group yields a quantisation of the dual Lie bialgebra as well. We extend this to a much more general result: namely, given any PID R for each prime $\hbar \in R$ we establish sort of an “inner” Galois’ correspondence on the category $\mathcal{HA}$ of torsionless Hopf algebras over R , via the definition of two functors (from $\mathcal{HA}$ to itself) such that the image of the first, resp. of the second, is the full subcategory of those Hopf algebras which are commutative, resp. cocommutative, modulo $\hbar$ (i.e. they are “*quantum function algebras*” (=QFA), resp. “*quantum universal enveloping algebras*” (=QUEA), at $\hbar$). In particular we provide a machine to get two quantum groups — a QFA and a QUEA — out of any Hopf algebra H over a field $\mathbb{k}$: just plug in a parameter ν and apply the functors to $\mathbb{k}[\nu] \otimes_{\mathbb{k}} H$ for $\hbar = \nu$. Several relevant examples (the semisimple groups, the Euclidean group, the Heisenberg group, and the Kostant-Kirillov structure on any Lie algebra), as well as an interesting application to quantum electro-dynamics, are studied in some detail.
